Background:	This gene encodes an enzyme involved in pyrimidine salvage. The encoded protein forms a homotetramer that catalyzes the irreversible hydrolytic deamination of cytidine and deoxycytidine to uridine and deoxyuridine, respectively. It is one of several deaminases responsible for maintaining the cellular pyrimidine pool. Mutations in this gene are associated with decreased sensitivity to the cytosine nucleoside an

alogue cytosine arabinoside used in the treatment of certain childhood leukemias.
